

5.3.6. Figure 5.6: Take-off Distance

Conditions:

- maximum take-off power
- take-off speed (speed for lift off and climb over the obstacle) 57 kts. / 65 mph / 105 km/h IAS
- level runway, paved
- flaps in take-off position (T/O)

Example:

- Pressure altitude: 3000 ft.
- Outside temperature: 15° C (59° F)
- Mass (Weight): 675 kg (1488 lbs.)
- Wind: 10 kts.

Result:

- Take-off roll distance: 330 m (1080 ft.)
- Take-off distance to clear a 15 m (50 ft.) obstacle: 470 m (1540 ft.)

NOTE

Poor maintenance condition of the airplane, deviation from the given procedures as well as unfavorable outside conditions (high temperature, rain, unfavorable wind conditions) could increase the take-off distance considerably. For take-off from dry, short-cut grass covered runways compared to paved runways, a 25% increase in take-off roll distance must be taken into account.

On soft grass covered runways with grass deeper than 10 cm (4 in.), the take-off roll distance might be increased by as much as 40%.

The dashed lines in the above diagram (wind component) represents tailwind.
